SECTION 1

INTRODUCTION

From 29 April to 2 May 2002 and 20 and 21 May 2002, United States Environmental Protection Agency (U.S. EPA) On-Scene Coordinator (OSC) Verneta Simon and the Weston Solutions, Inc. (WESTON®) Superfund Technical Assessment and Response Team (START) initiated a site assessment and extent of contamination investigation at the Calumet Container site located in Hammond, Lake County, Indiana. The site assessment activities were conducted under Technical Document Directive (TDD) S05-0202-001. The analysis of the samples collected during the site assessment was under TDD S05-0202-002.

1.1 OBJECTIVES AND SCOPE OF SITE ASSESSMENT

The objective of this site assessment was to gather information to characterize the nature and extent of soil contamination at the Calumet Container site.

To accomplish these objectives, the site assessment activities consisted of screening soil for lead content with x-ray fluorescence (XRF), collecting surface and subsurface soil samples from the site and selectively analyzing the samples for organic and inorganic parameters.

1.2 REPORT ORGANIZATION

This site assessment report is organized into the following sections.

- Introduction – The introduction provides a brief description of the objective and scope of the site assessment activities.
- Site Background – The site background section provides the site description, site history, and a summary of previous investigations.

- Environmental Investigation Procedures – The environmental investigation procedures section describes the methods and procedures used during the site assessment activities.
- Environmental Investigation Results – The environmental investigation results section describes the results of sample analysis.
- Nature and Extent of Contamination – The nature and extent of contamination describes the estimated areas and volume of contaminated site soils.
- Conclusions – The conclusions summarize the findings of the site assessment activities.
- References – The reference section provides a list of references utilized in compiling the report.
- Tables, Figures, and Appendices – The tables, figures, and appendices will be provided at the end of the report.

SECTION 2

SITE BACKGROUND

2.1 SITE DESCRIPTION

The Calumet Container site is located 3631 State Line Avenue in Hammond, Lake County, Indiana. The geographic coordinates of the site are 41° 38' 57" north latitude and 87° 31' 25" west longitude at an altitude of 476 feet above sea level. Approximately 90 percent of the 11-acre, triangular-shaped site is located in Lake County, Indiana and the remaining 10 percent is located in Cook County, Illinois (Figure 2-1). The site is bounded to the north by 136th Street, and in all other directions by the active Indiana Harbor Belt Railway. A chain-link and barbed-wire fence surrounds the site. Other key features on site include patches of dense, ground-cover vegetation and mature trees, an old building foundation, three abandoned tanker trucks and drums and overgrown piles of miscellaneous debris.

On 29 April 2002, a fence contractor for West Shore repaired the chain-linked fence along the pipeline right-of-way. Previously, access to the site was unrestricted due to the breaches in the fence. The chain-link and barbed-wire fence that surrounds the site has a locked gate on the north side, accessed by 136th Street. Along 136th Street, a 40-foot section of fence was collapsed by a pile of soil that had apparently been dumped onto it. Evidence of recent trespassing was still evident and included worn footpaths that cross the site, a fire ring surrounded by chairs and a pet grave with flowers and a flag adorning it, all of which was previously observed during the 20 February 2002 site assessment.

Large piles of scrap metal, tires and semi-trailer frames were seen on the site. START estimated the scrap metal from the semi-truck trailers to be approximately 420 cubic yards. The majority of the scrap metal is located on the northwest corner of the site with a few piles along the West Shore pipeline right-of-way in the middle of the site.

Both industrial- and residential-use land surrounds the site and within 1/4 mile of the site boundary are recreational-use bodies of water. A mobile home park is located directly adjacent to the site to the east and another is across 136th Street to the northwest. A small pond and wetland are situated in the northeast corner of the property. Across 136th Street to the north is Wolf Lake, an interstate fishing and recreational lake (Figure 2-2). Beyond the rail line to the southwest is Powderhorn Lake and the Burnham Woods forest preserve. Lake Michigan is located less than 3 miles to the northeast of the site.

Two studies have been done to evaluate ground- and surface-water flow patterns in the area of the site (Wapora, 1979 and Soil Testing Services, 1980). Both studies concluded that groundwater tends to flow in a northeast direction from the site. Intermittent ponded surface water at the site has been documented in historic site photographs and records. The movement of surface water off the site is not easily characterized; however, there may be a potential for surface water to flow off site towards nearby Wolf Lake, Powderhorn Lake, or a small stream to the northeast of the site that feeds Wolf Lake. In the past, recreational use of Wolf Lake has been impaired by, among other things, direct or indirect industrial discharges to the lake (U.S. EPA, 1981). A third study of site hydrogeology indicated that the water table is 3-4 feet below the ground surface (bgs)(King, 1979).

Soil types vary on site and adjacent properties. The unconsolidated layer of soil above bedrock in the area of the site is 90-100 feet thick and composed of 15-20 feet of beach and shoreline deposits interbedded with fine gravel, silt and clay over silty, sandy, clay till. It has been noted that the accumulation of oil and paint solids on the site may have acted to seal the soil surface in some areas and not allow percolation of surface water into the ground at those locations (King, 1979). A well log for an installation in the Burnham Woods forest preserve adjacent to Powder Horn Lake, southwest of the site, revealed that the upper 44-feet of soil is clay, followed by 118-feet of shale (Pankanin, 1982). The railroad grade along the eastern edge of the site is composed of fill material, slag, cinders, sand and gravel (King, 1979). North of the site, at the southern end of Wolf Lake are small areas of significant wetlands, classified as Type 4 Deep Marsh (U.S. EPA, 1981).

Service utilities were noted on the site property (Figure 2-2). An overhead electrical power line enters the property from 136th Street near the gate and terminates on the site at a control box that is mounted on a pole approximately 150 feet south of the gate. There is a buried West Shore petroleum pipeline on the site that runs east to west across the property under a cleared right-of-way. A buried Praxair Nitrogen pipeline also crosses the site. A geophysical report prepared for the Indiana Department of Environmental Management (IDEM) in 1986 indicated the presence of markers or breather pipes for Badger, Marathon, Amoco and Union Carbide pipelines on the site property (Bartlett and Ursic, 1986). According to the U.S. EPA files, there are no drinking water wells in the area that can be threatened by groundwater contamination in the area (Pankanin, 1982).

2.2 SITE HISTORY

The Steel Container Corporation, also known as the Calumet Container Corporation, began operations in the 1960's and was owned and operated by Mr. John Jagiella. Operations at the site included drum and pail reconditioning (5- to 55- gallon) and fiber drum processing. Most of the containers that were serviced were used in the paint and graphic arts industries. In July 1981, Mr. Jagiella filed for bankruptcy in Chapter 11 Federal Bankruptcy Court. The Lake County Commissioners currently own the bulk of the Calumet Container site that is located in Indiana. A small parcel of land in the northwest corner of the site is privately owned by Mr.

During the period that the Calumet Container Corporation facility was in operation, the company was cited with numerous environmental violations regarding air and water contamination and material disposal. In 1980, the Illinois State Attorney General began an investigation to evaluate the movement of groundwater from the site into Illinois (Bitter, 1984). It was determined that groundwater in the area of the site contained elevated levels of organic compounds, including phenolics, toluene, xylene, and PCBs, and heavy metals and that the groundwater had the potential to migrate into Illinois-owned soils and nearby Wolf Lake (Soil Testing Services, 1980). The State of Indiana Stream Pollution Control Board ordered Mr. Jagiella to clean up spilled residues on the

site and the owner was eventually issued a Final Order by the State of Indiana. Subsequent property inspections following the Final Order yielded violations of that Order and on 16 April 1982, the State of Indiana Attorney General filed an Enforcement Action against Calumet Container Corporation (Bitter, 1984).

Five days after the State of Indiana Enforcement Action was filed, on 21 April 1982, an explosion and fire consumed the main building at the site and the U.S. EPA began a 14-day Immediate Removal Action on 7 May 1982. Thirty cubic yards of sludge and 5,500 gallons of contaminated liquid were removed from the site and disposed of at that time. Analysis of surface water runoff, contents of processing and holding tanks on site and soil at the loading dock area at the time immediately following the fire indicated the presence of lead, chromium, cyanide, arsenic, phenolics, other organics, oil and grease. Following the fire, the U.S. EPA notified Mr. Jagiella and requested that he volunteer to clean up the site. Mr. Jagiella then attempted to organize a group of responsible parties to clean up the site, but failed to do so and as a result, the U.S. EPA initiated a cleanup (Madany and Bowden, 1982).

In accordance with section 104 (a) (1) CERCLA, a Planned Removal Action began at the site on 9 January 1984. U.S. EPA contractor Associated Chemical and Environmental Services of Oregon, Ohio, began a surface cleanup of containerized liquids, solids and sludges that were considered to be hazardous materials. A heavily contaminated area used as a loading dock during facility operation was completely dismantled and removed. Approximately 2-feet of soil was removed from underneath the loading dock and the area was backfilled and capped with 162 tons of clay. Other areas of the site that contained visibly stained soils were also excavated and backfilled with clay (Bitter, 1984).

A site assessment conducted by U.S. EPA and START on 20 February 2002 discovered that the site was littered with several drums, automobile and scrap metal debris, a plating vat, three tanker trucks, an old building foundation and paint chips and residue. A cluster of 14 drums was noted near the

north gate of the property. Five investigative soil samples and one drum sample were collected and analyzed for a variety of potential contaminants. Sampling results for metals analyses indicated levels of lead, chromium, and PCBs in site soils above U.S. EPA Region IX PRG criteria levels. Based on the results of TCLP analysis of site soils and according to 40 CFR Chapter 1 - 261.24, hazardous waste characteristics of lead and cadmium were detected in site soils. Material sampled from a drum at the site was determined to be hazardous waste based on its flashpoint. The flashpoint of the drummed material was 80 °F which exceeds the criteria for hazardous waste.

SECTION 3

ENVIRONMENTAL INVESTIGATION PROCEDURES

From 29 April to 2 May 2002 and 20 and 21 May 2002, a site assessment of the Calumet Container property was conducted by U.S. EPA and WESTON START personnel to determine extent of the contamination present in surface and subsurface soils. On-site personnel included OSC Verneta Simon (U.S. EPA) and Don Paxton, Todd Williams, Heather Schichtel, and Greg Gehrig (START). The investigation was conducted in two sampling events. Specific site assessment activities included:

- Site Layout
- XRF Screening
- Geoprobe Investigation and Soil Sampling
- Geoprobe Investigation and Sediment Sampling
- Geotechnical Sampling
- Wetland Delineation

3.1 SAMPLING ACTIVITIES

3.1.1 Site Layout

On 29 April 2002, a sampling grid was layed out to identify locations where Geoprobe core samples would be collected. A GPS was used to navigate from each location to the next, as well as record the GPS location of each point. The grid was created using a 100-foot grid spacing throughout the site. The triangular shape of the site and topographical obstacles such as the pond, trees, and large scrap piles necessitated using offsets from the proposed locations identified on the map used for the grid layout. Trees onsite made GPS reception difficult in some areas, causing some additional skewing of the site grid.

3.1.2 XRF Screening

A Niton XRF unit was used to screen 143 surface and sub-surface soil and sediment samples from 53 locations on site to determine the location of soil and sediment that contained elevated metal concentrations. Soil and sediment samples were retrieved by Geoprobe coring techniques. XRF screening depths were selected within each soil core to characterize the surface and subsurface soils. Each sample core was typically screened with two to four interval locations ranging from the surface to a 4-foot depth. Plastic zipper-locking bags were filled with sample material and then screened with the XRF unit during the first portion of the assessment, and during the second portion of the assessment the XRF unit was placed directly on the exposed soil in the acetate sleeve that was used to collect the soil core. The primary analyte of interest during the investigation was lead, although 13 other analytes are also detectable by the XRF unit. Screening results were datalogged with the XRF unit. At 13 screening locations, soil samples were collected from the depth interval that was screened and submitted for confirmatory laboratory analysis of lead content. The results of the confirmation sampling are further discussed in Section 4.2.1 of this report.

3.1.3 Surface and Subsurface Soil Sampling

During the 29 April to 2 May 2002 and 20 and 21 May 2002 Site Assessment, 26 investigative surface and subsurface soil samples were collected in order to define the native soil and extent of contamination on site. Samples were collected from selected grid locations and five biased, non-grid locations. Offsets were used in some locations where obstacles were encountered. Sample collection locations are shown in Figure 3-1.

Samples were collected using an ATV-mounted Geoprobe. The ATV-mounted Geoprobe drives a 4-foot long, 2-inch diameter hollow sampling rod into the ground by means of a motor-driven hydraulic hammer. After the rod has been driven into the soil to the desired depth, the motor is reversed to remove the sampling rod. The hollow rods are lined with an acetate insert to collect

samples and help preserve the cleanliness of the rod interior. After the rod was extracted from the ground, the acetate insert was removed, cut open lengthwise so contents could be observed, geologically logged, and sampled. Geoprobe boring logs are provided in Appendix A.

A total of 26 investigative surface and subsurface soil samples were collected [CC-(0,0) 1'-2', CC-(0,1) 1'-2', CC-(0,2) 1'-2', CC-(0,3) 1'-2', CC-(0,4) 1'-2', CC-(0,10) 3'-4', CC-(0.5, 2.5) 1'-2', CC-(0.5,2.5) 3'-4', CC-(1,2) 2'-3', CC-(1,3) 1'-2', CC-(1,5) 1'-2', CC-(1,7) 1'-2', CC-(1,8) 3'-4', CC-(1,9) 3'-4', CC-(2,3) 1'-2', CC-(2,4) 1'-2', CC-(2,8) 0-6", CC-(2,8) 2'-4', CC-(3,5) 1'-2', CC-(3,7) 1'-2', CC-(3,8) 0-1', CC-(3,10) 0-2', CC-(4,7) 1'-2', CC-(5,6) 0-6", CC-(5,7) 1'-2', and CC(6,7) 3'-4']. Soil samples were collected from the acetate core liners and placed into clear, wide-mouth, glass jars with Teflon-lined lids. Sterile nitrile gloves were donned before the first sample was collected and changed before each subsequent sample. Soil cores were generally collected from 0 to 4 feet below ground surface (ft. bgs) with the exception of one Geoprobe core located at point CC-(0.5, 2.5) which was collected from 0 to 8 ft. bgs. The sample intervals selected for analysis were biased based on Multi-RAE VOC readings, presence of odors, XRF readings, and the presence of paint chips or colored materials (blue, yellow, green, etc.).

Seventeen samples were collected for analysis of selected organic compounds. Once the sampling depth was determined for a soil core, a grab sample was first collected for volatile organic compounds (VOCs) using a disposable EnCore sampler. VOC sampling was followed by the collection of a sample for semi-volatile organic compounds (SVOCs), pesticides and polychlorinated biphenyls (PCBs). Sample aliquots for individual parameters were consistently collected in this order to minimize volatilization of organic compounds prior to sample collection. Ten samples were analyzed for VOCs, SVOCs, pesticides and PCBs [CC-(0,3) 1'-2', CC-(0,4) 1'-2', CC-(1,3) 1'-2', CC-(1,7) 1'-2', CC-(2,4) 1'-2', CC-(2,8) 2'-4', CC-(3,5) 1'-2', CC-(3,10) 0-2', CC-(5,7) 1'-2', and CC-(6,7) 3'-4'], and seven samples were analyzed for VOCs only [(CC-(0,0) 1'-2', CC-(0,1) 1'-2', CC-(0,2) 1'-2', CC-(0.5,2.5) 3'-4', CC-(1,2) 2'-3', CC-(1,5) 1'-2', and CC-(2,3) 1'-2']. During the second sampling event, 20 and 21 May 2002, two soil samples [CC-(1,2) 2'-3' and CC-(0.5,2.5) 1'-2'] were analyzed

for benzene, toluene, ethylbenzene, and xylene (collectively known as BTEX) compounds instead of for VOCs, SVOCs, PCBs and pesticides because laboratory results from the previous sampling event revealed a predominance of BTEX compounds relative to other organic compounds.

In addition to organic compounds, three soil samples were also sampled for Target Analyte List (TAL) metals [CC-(2,8) 2'-4', CC-(3,10) 0-2', and CC(6,7) 3'-4'] and an additional five investigative soil samples were analyzed for TAL metals only [CC-(1,8) 3'-4', and CC-(1,9) 3'-4', CC-(3,7) 1'-2', CC-(3,8) 0-1', and CC-(4,7) 1'-2']. Five investigative soil samples were collected for lead only, as a supplement to those samples that were analyzed for TAL metals, for the purpose of confirming lead-in-soil contents as determined by XRF screening [CC-(0, 10) 3'-4', CC-(0.5, 2.5) 1'-2', CC-(1, 2) 2'-3', CC-(2, 8) 0-6", and CC-(5, 6) 0-6"].

All samples were labeled and preserved in coolers with ice immediately after sample collection. At the end of the sampling period, samples were packed, transported, and relinquished under chain of custody to ACE Technologies, Inc. located in The Woodlands, Texas and Accura Analytical Labs, Inc. located in Norcross, Georgia for analysis.

Spent personal protective equipment (PPE) and contaminated debris that was generated during the sampling event were containerized in a 55-gallon drum at the site and labeled "PPE".

3.1.4 Sediment Sampling

Three sediment cores were collected using a Geoprobe along the perimeter of the pond, which is located in the northeast corner of the site, to determine if contaminants have migrated into the pond. Each core was geologically logged. Core SD-01 was collected from the northwest side of the pond, core SD-02 was collected from the west side, and core SD-03 was collected from the southwest side. Sediment cores were screened with an XRF and Multi-RAE and logged in the same manner as the

soils samples. One sediment sample taken from core SD-02 [CC-(SD-02) 0-1'] was analyzed for lead as confirmatory analysis for comparison to XRF screening results.

3.1.5 Geotechnical Sampling

Geotechnical sampling was conducted to determine the potential for future uses of the site such as the placement of a state road along the western boundary of the site. Five soil samples were collected using a Geoprobe for analysis of geotechnical parameters. Sample collection locations are shown in Figure 3-1. Geotechnical samples were collected in 24-inch-long, 3-inch-diameter Shelby soil collection tubes from grid locations (1, 10), (1, 8), (1, 6), (1, 5), and (1.5, 3.5). The tube was advanced 24-inches or to refusal, starting from where native soil was observed. On the northern portion of the site where samples were collected, native soils were observed at the surface. On the southern portion of the site where fill was present, native soils were observed approximately two feet bgs. Samples were analyzed for grains size, particle distribution, United States Geological Survey (USGS) Soil Conservation Survey soil classification, moisture content, organic content, specific gravity, density, and Atterburg limits. Samples were sent to CGC, Inc. located in Madison, Wisconsin for geotechnical analysis.

3.1.6 Wetland Delineation

On 20 May 2002, a wetland investigation of the approximately 11-acre site was performed. The purpose of this investigation was to identify, delineate, and determine the quality of the wetlands and other waters present onsite. Wetlands and other waters were identified and delineated at the site using a United States Army Corps of Engineers Wetland Delineation Manual (Environmental Laboratory, 1987) defined method and best professional judgment. A GPS unit and a digital camera were used to document wetland features observed onsite.

SECTION 4

ENVIRONMENTAL INVESTIGATION RESULTS

A Site Assessment was performed to determine the extent of contamination at the Calumet Container site. This section discusses the results of the site assessment activities listed below:

- XRF Screening
- Surface and Subsurface Soil Sampling
- Sediment Sampling
- Geotechnical Sampling
- Wetland Delineation

4.1 XRF SCREENING

XRF screening was conducted on 143 samples, at surface and subsurface intervals, from 53 sample locations. Screening results for lead concentration in soil are presented in Table 4-1. Results indicated that 26 soil samples contained lead concentrations that exceeded 800 ppm. The highest lead concentration detected by XRF (6,848 ppm) was found at location CC-(5,7), approximately 2 feet bgs. Thirteen of the locations that were screened by XRF were selected for lead analysis by wet chemical methods. Results of the confirmation analysis are presented with corresponding field XRF results and determinations of data accuracy and correlation in Table 4-2. A complete listing of XRF field data is presented in Appendix B.

The correlation of the XRF data for lead concentration and the results of the wet chemical analysis technique appear to be within the XRF unit's statistical comparison of precision (\pm factor) for several samples. For example, at location CC-(3,7), XRF analysis determined that the lead concentration in the soil was 157.8 ± 90.5 parts per million (ppm) or mg/kg, and laboratory analysis on the same sample determined that the lead concentration was 133 mg/kg. The result of the laboratory confirmation falls within the predicted range of precision for the XRF unit. At location CC-(3,8) the XRF result was 752 ± 74.4 mg/kg, and the laboratory result was 805 mg/kg. Again,

the laboratory confirmation falls within the predicted range of precision for the XRF unit. Other sample results did not correlate well. Relative percent difference (RPD) ranged from 3 percent to 94 percent between XRF and laboratory results. Instances of poor correlation between XRF and laboratory results was likely due to the "nugget effect" whereby the high or low level was encountered from the presence of a piece of the constituent during either the XRF screen or the laboratory analysis. A variance is observed between the results of the two techniques when the "nugget" is only encountered during one of the analyses, either the XRF screen or the laboratory technique.

4.2 SURFACE AND SUBSURFACE SOIL SAMPLING RESULTS

Twenty-six investigative soil samples were collected from 24 locations during this investigation and submitted for laboratory analysis. Analytical parameter selections for each sample are outlined in Section 3.2. Results for these analyses were compared to regulatory criteria levels and presented in Tables 4-3 through 4-6. Three sets of criteria were used for comparison in the data presentation; U.S. EPA Region IX Preliminary Remediation Goals (PRGs), the State of Indiana Risk Integrated System of Closure (RISC) cleanup protocols, and the Illinois Environmental Protection Agency (IEPA) Tiered Approach to Corrective Action Objectives (TACO). Criteria levels for industrial-use land were used to evaluate the data. Figure 4-1 shows sample locations, analytical results, and XRF screening results that exceeded the criteria. Analytical results are presented in Appendix C.

4.2.1 Metals in Soil

Surface and subsurface soils were sampled at eight locations and submitted for TAL metals analysis [CC-(1,8) 3'-4', and CC-(1,9) 3'-4', CC-(2,8) 2'-4', CC-(3,7) 1'-2', CC-(3,8) 0-1', CC-(3,10) 0-2', CC-(4,7) 1'-2', and CC-(6,7) 3'-4']. Seven out of fourteen investigative samples had concentrations of lead or other metals that were above industrial criteria levels (Table 4-3).

Lead concentrations in the samples ranged from 2.8 mg/kg to 13,000 mg/kg. Lead concentrations exceeded the criteria level (1,000 mg/kg) at six sampling locations [CC-(0.5,2.5) 1'-2', CC-(1,2) 2'-3', CC-(1,9) 3'-4', CC-(2,8) 2'-4', CC-(3,10) 0-2', and CC-(6,7) 3'-4']. The highest concentrations of lead were detected at the following sampling locations:

- CC-(1,9) 3'-4' (13,000 mg/kg); and
- CC-(0.5,2.5) 1'-2' (6,520 mg/kg).

Concentrations of cadmium in soils ranged from undetectable to 27,000 mg/kg. Cadmium concentrations exceeded the criteria level (10,000 mg/kg) in soils at two sampling locations:

- CC-(3, 10) 0-2' (27,000 mg/kg); and
- CC-(1, 9) 3'-4' (21,000 mg/kg).

Concentrations of arsenic in soils ranged from undetectable to 280 mg/kg. Arsenic concentrations exceeded the criteria level (20 mg/kg) in soils at three sampling locations:

- CC-(3,10) 0-2' (280 mg/kg);
- CC-(3,7) 1'-2' (64.9 mg/kg); and
- CC-(2,8) 2'-4' (45 mg/kg).

Chromium and iron criteria were also exceeded at two soil sampling locations. Concentrations of chromium ranged from 1.0 mg/kg to 780 mg/kg and exceeded the criteria level (448 mg/kg) at sampling location CC-(3,7) 1'-2' (780 mg/kg). Iron concentrations in soil ranged from 3.36 mg/kg to 120,000 mg/kg, exceeding the criteria level (100,000 mg/kg) only at sampling location CC-(3,7) 1'-2' (120,000 mg/kg).

4.2.2 VOCs and BTEX in Soil

Seventeen surface and subsurface soil samples were analyzed for VOCs or BTEX. The results from these analyses in site soils are presented in Table 4-4 and Figure 4-1. Results indicate that VOCs or BTEX were detected at concentrations that exceeded the criteria levels at six sampling locations

[CC-(0,0) 1'-2', CC-(0,1) 1'-2', CC-(0,2) 1'-2', CC-(0,3) 1'-2', CC-(1,5) 1'-2', and CC-(2,4) 1'-2']. Individual VOCs that exceeded criteria levels on site were: ethylbenzene, total xylenes, toluene and 1,2-dichloropropane. Ethylbenzene concentrations in soil samples ranged from undetectable to 970,000 ug/kg. Those concentrations of ethylbenzene that exceeded the criteria level (230,000 ug/kg) were the following:

- CC-(1,5)1'-2' (970,000 ug/kg);
- CC-(0,1) 1'-2' (750,000 ug/kg);
- CC-(0,2) 1'-2' (620,000 ug/kg); and
- CC-(0,3) 1'-2' (390,000 ug/kg).

Total xylenes concentrations in soil samples ranged from undetectable to 4,200,000 ug/kg. At the following five sampling locations, concentrations of total xylenes were detected at levels greater than the criteria level (210,000 ug/kg):

- CC-(0,1) 1'-2' (4,200,000 ug/kg);
- CC-(1,5)1'-2' (3,200,000 ug/kg);
- CC-(0,2) 1'-2' (2,300,000 ug/kg);
- CC-(0,3) 1'-2' (1,700,000 ug/kg); and
- CC-(0,0) 1'-2' (240,000 ug/kg).

Toluene concentrations in site soils ranged from undetectable to 8,400,000 ug/kg. Concentrations of toluene exceeded the criteria level (520,000 ug/kg) at the following three sampling locations:

- CC-(0,1) 1'-2' (8,400,000 ug/kg);
- CC-(0,2) 1'-2' (3,600,000 ug/kg); and
- CC-(1,5) 1'-2' (1,200,000 ug/kg).

Concentrations of 1,2-dichloropropane in site soils ranged from undetectable to 2,600 ug/kg. One sample, at location CC-(2,4) 1'-2' depth (2,600 ug/kg), exceeded the criteria level for 1,2-dichloropropane (800 ug/kg).

4.2.3 SVOCs in Soil

Ten surface and subsurface soil samples were analyzed for SVOCs. The results are presented in Table 4-5 and Appendix C. Criteria levels were not exceeded by any SVOCs in these samples. Three SVOCs were detected above method limits: 2-methylnaphthalene, bis(2-ethylhexyl)phthalate and naphthalene. The greatest concentrations of these SVOCs were detected in the following samples: CC-(1,7) 1'-2', (4,700 ug/kg of 2-methylnaphthalene), CC-(0,3) 1'-2' (14,000 ug/kg of bis(2-ethylhexyl)phthalate), and CC-(1,7) 1'-2' (8,300 ug/kg of naphthalene).

4.2.4 PCBs and Pesticides in Soil

Ten surface and subsurface soil samples were analyzed for PCBs and pesticides. PCB analytical results are displayed in Appendix C. No PCB compounds were detected in any of the samples. Pesticide results are displayed in Table 4-6. No pesticide compounds were detected above criteria levels in these samples. The pesticides at greatest concentrations in soil were found at the following site locations: CC-(0, 4) (220 ug/kg of 4,4-DDT), CC-(3, 5) (94 ug/kg of Chlordane), and CC-(2-9) 2'-4' (50 ug/kg of 4,4'-DDE).

4.3 SADA SOFTWARE USE FOR VISUALIZATION OF ON-SITE EXTENT OF CONTAMINATION AND HUMAN HEALTH RISK

Spatial Analysis and Decision Assistance (SADA) software was used to further illustrate the extent of contamination as shown in Figure 4-1 and visually assess the risk to human health. The color-scaled, two-dimensional diagrams produced by the SADA software makes visualizing contamination easier and is a useful tool for communicating analytical results to interested parties. Each SADA plot presented in Appendices E and F represents the area of the site with overlays of the concentration of specific parameters (Appendix E) and an estimate of the human health risk that is based on contaminant concentrations (Appendix F). Concentrations of contaminants in surface soil

or sediment were used to generate each plot, except in the cases where a subsurface sample had a greater concentration of contaminant than the surface soil at the same location. In these cases, the highest concentration of the contaminant at depth was used. For samples that had concentrations below the method limits of detection, one half of the detection limit was used to represent the sample concentration, with the exception of benzene. Undetectable levels of benzene were assumed to have a concentration of zero.

Extent of contamination figures generated by SADA software are presented in Appendix E for all constituents that exceed screening levels (i.e., ethylbenzene, m-p xylene, o-xylene, benzene, toluene, 1,2-dichloropropane, arsenic, cadmium, chromium, iron, and lead). It should be noted that the color scale for each figure denotes relative concentration of the contaminant and does not necessarily reflect the concentration of the contaminant relative to criteria levels or remediation goals. Ethylbenzene, m-p xylene, benzene, toluene, 1, 2-dichloropropane and lead concentrations are clearly shown in the SADA plots to be greater in the southwest corner of the site than other areas of the site. Likewise, o-xylene is shown to be relatively high in the east corner of the site and areas of relatively high metals concentrations (lead, arsenic, cadmium, chromium and iron) are evident in the northern third of the site, including the northwest and east corners. Similar patterns are found in Figure 4-1 where analytical data is plotted directly onto a site map.

SADA provides a human health risk assessment module to calculate the risk of adverse health impacts on a population exposed to toxic chemicals found in groundwater, surface water, soil, and sediment (*Spatial Analysis and Decision Assistance (SADA) Version 2.3 User Guide*, January 2002. <http://www.tiem.utk.edu/~sada/>). (See Appendix G). The toxicological parameters included with SADA were taken from the United States Environmental Protection Agency's (EPA's) Integrated Risk Information System (IRIS) and the Health Effects Assessment Summary Tables (HEAST). For a given set of values, SADA finds the minimum of the 95 percent upper confidence limit (UCL95) and the maximum detected value, and using this exposure concentration, SADA calculates risk based on the contaminant and the exposure scenario. For this site, the industrial scenario was evaluated.

Under the industrial scenario, industrial workers are expected to be routinely exposed to contaminated media within a commercial or industrial setting. The future industrial scenario is evaluated using default values provided by EPA for the ingestion, dermal contact, and inhalation exposure routes. Soil exposures are also based on the potential for the use of heavy equipment and related traffic in and around the contaminated soil and sediment. Therefore, soils and sediment could be disturbed, producing particulate emissions. It should be noted that the assumptions and default parameters for the industrial land use scenario do not reflect the use of protective clothing or other safety precautions.

The risk to human health due to the presence of chemicals that exceed screening levels (i.e., ethylbenzene, m-xylene, o-xylene, benzene, toluene, 1,2-dichloropropane, arsenic, cadmium, and chromium) on site can be visualized with the assistance of the SADA plots in Appendix F. Lead and iron are not evaluated using SADA due to the lack of toxicity values (i.e., slope factor or reference dose). The plots assume future unrestricted residential land use, and that the contaminants pose an ingestion or inhalation risk. Note that the color scale refers to an index number that corresponds to the amount of risk present at locations around the site. Generally, for compounds that are potential carcinogens, a risk is present if the index is greater than 1×10^{-6} ; an acceptable risk is described with an index between 1×10^{-6} and 1×10^{-4} ; and a high level risk is described with an index greater than 1×10^{-4} . Benzene, 1,2-dichloropropane, arsenic, cadmium, and chromium are potential carcinogens, though cadmium and chromium are carcinogenic only through the inhalation route. The other contaminants under investigation, ethylbenzene, m-xylene, o-xylene, and toluene are non-carcinogenic and are therefore only considered a health risk if the hazard index is greater than one. Resultant human health risk indices are presented in Table 4-6.

The figures in Appendix F display the same trends as the figures in Appendix E that present the concentration of contaminants on site. That is, where the concentration of each contaminant is greater, the index of risk is greater. Highest levels of carcinogenic risks are present in areas of high concentrations of arsenic (north central site) and 1,2-dichloropropane (southwest corner of site).

High level risk index values for ingestion and inhalation exposure pathways range from 2.77×10^{-4} to 176 in these areas due to the presence of arsenic and 1,2-dichloropropane.

Highest levels of non-carcinogenic risk due to ingestion are present in the both the southwest corner of the site and the northern third of the site. Risk indices for these locations range from 1.28 to 41.1 due to high levels of arsenic, cadmium, ethylbenzene, m-p xylenes and toluene.

4.4 GEOTECHNICAL SAMPLING

A total of five individual 3-inch diameter Shelby Tube (ST) soil samples were collected at the site. The ST soil samples were collected from 0 to 4 feet total depth. The ST soil samples were analyzed for percent moisture, percent organic content (%), and percentage of grain size distribution. The Atterburg limits analysis was not performed by the laboratory due to the soil type. The analytical results of the five individual ST soil samples were analyzed by CGC, Inc. of Madison, Wisconsin.

The analytical results indicated soils composed primarily of brown, fine-grained sands. The sand content of the soil samples ranged from 80 to 95.9% in four of the five ST soil samples collected. The ST soil sample collected at sampling location CC-(1, 6) contained a higher percentage of silt at 50.4% total silt. The moisture content of the sand was between 19.1 and 25.2%. The total organic content was between 1.2 and 3.9 %.

The particle size analysis generated by the ST soil samples indicates that the soil is primarily well-drained fine sand. Fine-grained sands of this type are a typical material used in the base of most roads. However, with the porous nature of the material and unknown site hydrologic conditions, it is recommended that a test of the sand's strength be performed prior to paving the surface of the site. A strength test will determine how much load the sand could hold per square foot and if it could support road traffic. The geotechnical results are presented in Appendix D.

4.5 WETLAND DELINEATION

The 11-acre site is comprised of approximately 5.15 acres of forested, scrub/shrub and emergent wetlands were identified and delineated on the site. These wetlands were found along the southeastern edge and the northern half of the property. The wetlands are primarily a mixture of emergent and scrub/shrub systems that grade to a forested wetland system as you proceed northwest towards 136th Street and the adjacent property. An open water/wetland complex is located in the eastern point of this triangular property. No streams or ditches were identified on the site. Wetland areas are illustrated in Figure 4-2.

Four wetland areas were delineated at the site. Wetland Area 1 consisted of several points around a small pond and an associated wetland complex. Wetland Area 2 consisted of several points along the southeastern border of the property. Wetland Area 3 is a small depression at the southern part of the property adjacent to the former building complex. Wetland Area 4 which is located along the northern portion of the site, is a large wetland complex that encompasses approximately 40 % of the property. Three small areas of upland and fill were surveyed within Wetland Area 4 with GPS and are noted on the wetland delineation map as being non-wetland areas. Further details are documented in the June 2002 Wetland Delineation Report generated by WESTON.

SECTION 5

NATURE AND EXTENT OF CONTAMINATION

The objective the site assessment was to evaluate the nature and extent of contamination, in order that an informed decision could be made regarding the level of that is presented by contaminants on site and the appropriate type of removal action(s) necessary. For the assessment, field data was collected and compared to screening levels to delineate the extent of contamination on site. The following discussion addresses the nature and extent of contamination in the site surface and subsurface soils.

To determine the nature and extent of contamination, analytical results were compared to U.S. EPA Region IX Preliminary Remediation Goals (PRGs), the State of Indiana RISC cleanup protocols, and the Illinois Environmental Protection Agency (IEPA) Tiered Approach to Corrective Action Objectives (TACO). Criteria levels for industrial-use land were used to evaluate the data. Concentrations of four VOCs and five metals in site soils exceeded criteria levels. The VOCs that appeared in concentrations that exceeded the criteria levels include ethylbenzene, m/p-xylenes (total xylenes), toluene, and 1,2-dichloropropane. Concentrations of lead, cadmium, chromium, arsenic, and iron exceeded the criteria for metals contamination.

5.1 VOC Extent of Contamination

Estimates of the area, depth, and volume of soil contaminated with VOCs were generated by determining sample locations that had metals concentrations that exceeded criteria levels, and then estimating both a surface area and depth of contamination. As determined by laboratory results and displayed in Figure 4-1, a large area in the southern portion of the site is contaminated with VOCs. In order to approximate a surface area on the map that would represent the contaminated soil, all data points that identified VOC contaminated soil were identified and the contamination in the areas between data points were extrapolated. Contamination was assumed to radiate out from a location

that contained contaminated soil for a distance that was half of the way to the nearest location where contaminant levels were less than criteria levels. The area of the site that is contaminated with VOCs is estimated to be 69,373 square feet (ft²). A graphic representation of the area is provided in Figure 5-1.

An estimate of the volume of VOC contaminated soil on site can be made by using the areal extent of VOC contaminated soil and an average depth of contamination. Depth of contamination was determined by inspecting the boring logs for each sample location (Appendix A). The depth of contamination was determined to be the depth below which no obvious visible soil staining or elevated levels of VOCs in the air inside the boring were noted during logging. However, if the soil sample taken from that location that was determined to be contaminated was collected from a depth deeper than this horizon, then the sample depth was used as the depth of contamination. Sample depth was also used for depth of contamination if no staining or elevated VOC levels were noted at the location. A depth of contamination was determined for each sample location included in the contaminated area. The average depth of contamination for VOCs on site is approximately 30 inches. Note that the water table in this region is present at three to four feet bgs (see Section 2.1). The average depth of VOC contamination, 30 inches, was used to calculate the volume of VOC contaminated soils on site. The total volume on site of VOC contaminated soil is 6,423 cubic yards (yd³).

5.2 Metals Extent of Contamination

Estimates of the area and volume of soil contaminated with metals were generated in a similar manner as was used to determine the extent of VOC contamination on site. Both laboratory and field results were used to identify contaminated areas of the site; that is, the analytical data (for all metals) and the field XRF data (for lead only). As displayed in Figure 4-1, a large portion of the site had consistently high levels of lead, chromium, cadmium, arsenic and iron. The same method of data extrapolation between sample points was used as was described in Section 5.1.. The area of the site

that is contaminated with metals is estimated to be 178,110 ft². A graphic representation of the area is provided in Figure 5-2.

By using the area of the site that contains metals contaminated soil and an average depth of contamination, an estimate of the volume of metals contaminated soil on site can be determined. Depth of metals contamination was determined by inspecting the boring logs for each sample location (Appendix A). If fill material was present at the sample location, the maximum depth of the fill material was used as the depth of contamination. However, if the soil sample taken from that location was collected from a depth deeper than the fill layer, then the sample depth was used as the depth of contamination. Sample depth was also used for depth of contamination if no fill material was present at the location. A depth of contamination was determined for each sample location included in the contaminated area. The average depth of contamination for metals on site, by this method, is approximately 31 inches. Based on an areal extent of metals contaminated soil of 178,110 ft² and depth of 31 inches the total volume of metal contaminated soil is 17,041 yd³.

5.3 Volume Estimate of Soil Contaminated with Comingled Waste

Portions of the two areas determined to be contaminated with either VOCs or metals overlap. An overlay of the two areas is shown in Figure 5-3. By delineating the areas that overlap and those that do not, separate volume estimates can be made for different types of soil contamination on site:

- the estimated volume of soil contaminated with VOCs only is 2,207 yd³;
- the estimate volume of soil contaminated with metals only is 12,684 yd³; and
- the estimated volume of soil contaminated with comingled waste is 4,357 yd³.

The total volume of contaminated soil on site is approximately 19,250 yd³.

SECTION 6

CONCLUSIONS

The Calumet Container site is located in Hammond, Lake County, Indiana. Approximately 90 percent of the 11-acre site is located in Lake County, Indiana and the remaining 10 percent is located in Cook County, Illinois. The Calumet Container Corporation occupied the site from the time it began operations in the 1960's until it closed permanently due to a catastrophic fire on 21 April 1982. Operations at the site included drum and pail reconditioning and fiber drum processing. Both industrial- and residential-use land surrounds the site. A small pond and wetland is situated in the northeast corner of the property and across 136th Street to the north is Wolf Lake, an interstate fishing and recreational lake. Mobile home parks are located to the east and northwest of the site, and to the southwest is Powderhorn Lake and the Burnham Woods forest preserve. Lake Michigan is located less than 3 miles to the northeast of the site. Most of the site is enclosed by a fence, but access to the site is unrestricted through a fence-break and evidence of trespassing is apparent.

The 11-acre site is comprised of approximately 5.15 acres of forested, scrub/shrub and emergent wetlands which were identified and delineated on the site. These wetlands were found along the southeastern edge and the northern half of the property. The wetlands are primarily a mixture of emergent and scrub/shrub systems that grade to a forested wetland system at the northwest portion of the site and adjacent property. An open water/wetland complex is located in the eastern point of this triangular property.

A site assessment was conducted on 20 February 2002, and investigators discovered that the site was littered with large amounts of drum, automobile and scrap metal debris, a plating vat, three tanker trucks, an old building foundation and paint chips and residue. A cluster of 14 drums was noted near the north gate of the property. Five investigative soil samples and one drum sample were collected and analyzed for a variety of potential contaminants. Analytical results indicated that the drummed sample was hazardous, based on flammability and elevated concentrations of metals were present in soil samples.

On 29 April to 2 May 2002 and 20 and 21 May 2002, a site assessment of the Calumet Container property was conducted by WESTON START personnel to determine the surface and subsurface

extent of the contamination onsite.

Twenty-two investigative surface and subsurface soil samples were collected from 53 boring locations on the site. Samples were analyzed for metals, VOCs, SVOCs, PCBs, and pesticides. To determine the nature and extent of contamination, analytical results were compared to U.S. EPA Region IX Preliminary Remediation Goals (PRGs) and the State of Indiana Risk Integrated System of Closure (RISC) cleanup protocols. Criteria levels for industrial-use land were used to evaluate the data. Five metals and four VOCs were found at concentrations that exceeded criteria levels. Concentrations of lead, cadmium, chromium, arsenic and iron exceeded metals criteria, and ethylbenzene, toluene, m/p-xylene (total xylenes), and 1,2-dichloropropane exceeded VOC criteria levels. The criteria exceedences for VOCs and metals were observed in one large area on the southern portion of the site, and in addition, metals contamination extended throughout a large portion of the entire site.

Surface areas representing contamination on site and corresponding volumes of contaminated soil were estimated for both metal- and VOC-contaminated soils. Approximately 2,207 yd³ of soil is considered to be contaminated due to high concentrations of VOCs only, approximately 12,684 yd³ of soil is considered to be contaminated due to high concentrations of metals only; and 4,357 yd³ of soil is considered to be contaminated by comingled waste, that is both VOCs and metals. The total volume of contaminated soil on site is approximately 19,250 yd³.

A total of five individual 3-inch diameter Shelby Tube (ST) soil samples were collected at the site. The ST soil samples were collected from 0 to 4 feet total depth. The particle size analysis generated by the Shelby Tube soil samples indicates that the soil is primarily well-drained fine sand. Fine-grained sands of this type are a typical material used in the base of most roads. However, with the porous nature of the material and unknown site hydrologic conditions, it is recommended that a test of sand strength be performed prior to paving the surface of the site. A strength test will determine how much load the sand could hold per square foot and if it could support road traffic.

Table 4-7

**Risk Indices for Residential Land Use, Carcinogenic and Non-Carcinogenic Endpoints, Inhalation and Ingestion Exposure Pathways
Calumet Container Site, Hammond IN**

	Parameter	Risk Pathway	Range of Risk Index low high
Residential/ Carcinogenic	arsenic	Ing	9.16x10 ⁻⁶ to 6.58x10⁻⁴
	arsenic	Inh	5.22x10 ⁻⁹ to 3.75x10 ⁻⁷
	cadmium	Inh	1.06x10 ⁻¹⁰ to 1.51x10 ⁻⁵
	chromium	Inh	3.74x10 ⁻⁹ to 2.91x10 ⁻⁶
	1,2-dichloroethane	Ing	0 to 1.2x10 ⁻¹⁰
	1,2-dichloroethane	Inh	0 to 1.2x10 ⁻¹⁰
	benzene	Ing	0 to 3.65x10 ⁻⁷
Residential/ Non- Carcinogenic	arsenic	Ing	1.78x10 ⁻² to 1.28
	cadmium	Ing	2.6x10 ⁻⁴ to 37
	chromium	Ing	4.57x10 ⁻⁴ to 3.56x10 ⁻¹
	ethylbenzene	Ing	3.62x10 ⁻⁵ to 9.49
	m-p-xyelene	Ing	3.47x10 ⁻⁵ to 2.05
	o-xylene	Ing	0 to 8.81x10 ⁻³
	toluene	Ing	1.81x10 ⁻⁵ to 41.1

Highlighted carcinogenic risk indices indicated that there is a high level risk present (greater than 1x10⁻⁴)

Highlighted non-carcinogenic risk indices indicate that there is a risk present (greater than one).

Ing = ingestion risk

Inh = inhalation risk

Grain size distribution curve for a sample of sand. The graph plots Percent Finer (0 to 100) against Grain Size in mm (500 to 0.001) on a semi-logarithmic scale. The curve shows a sharp drop in percent finer between 0.425 mm and 0.075 mm, indicating a well-sorted sand. The data points are plotted as open circles and connected by a solid line.

The graph displays a grain size distribution curve for a soil sample. The Y-axis represents the percentage of soil finer than a given grain size, ranging from 0 to 100. The X-axis represents the grain size in millimeters on a logarithmic scale, ranging from 500 mm to 0.001 mm. The curve starts at 100% finer for grain sizes down to approximately 10 mm, then gradually decreases, passing through approximately 85% finer at 1 mm, and dropping sharply to about 25% finer at 0.075 mm. Below 0.075 mm, the percentage finer continues to decrease more slowly, reaching approximately 1% finer at 0.001 mm.

APPENDIX G

SADA HUMAN HEALTH DOCUMENTATION

(Spatial Analysis and Decision Assistance (SADA) Version 2.3 User Guide. January 2002.

<http://www.tiem.utk.edu/~sada/>.

In SADA, four land use scenarios are considered: residential, recreational, industrial, and agricultural. The exposure pathways are grouped by soil-based exposure pathways (soil, and sediment) and by water-based exposure pathways (surface water and groundwater). The tables presented for each pathway list the default values that are in SADA. They can be changed by the user as needed to reflect updated guidance or site-specific conditions.

1 Land Use Scenarios

The four land use scenarios considered in SADA are future unrestricted industrial, residential, recreational, and agricultural exposures. The purpose of evaluating future land use scenarios as part of the risk assessment is to establish whether remedial action is necessary for alternate land uses by determining if the cumulative risk or hazard index from the source areas could exceed levels of concern. The future land use scenarios are based on the assumption that unrestricted industrial workers, residents, farmers, or recreational users of the area could be exposed. Current contaminant concentrations are used for the on-site assessment of future exposure. This represents a maximum exposure to contaminants in the area and will serve to define the potential human health risks that would exist if residential, unrestricted industrial, or recreational occupation were to begin within a short time frame.

Under the industrial scenario, industrial workers are expected to be routinely exposed to contaminated media within a commercial area or industrial site. The future industrial scenario is evaluated using industrial default occupational values provided in EPA. Pathways are evaluated for exposures to surface soil, sediment, and surface water. The exposures are based on the potential for the use of heavy equipment and related traffic in and around the contaminated soil and sediment in an unrestricted industrial scenario. Therefore, soils and sediment could be disturbed, thereby producing particulate emissions which could then be inhaled by the industrial worker. It should be noted that the assumptions and default parameters for the industrial land use scenario do not reflect the use of protective clothing or other safety precautions. The drinking water pathway to surface water (based on 1 L/day ingestion) is also evaluated for future industrial land use, though it is unlikely.

Under the residential land use scenario, future residents are expected to be in frequent, repeated contact with contaminated media. The assumptions in this scenario account for daily exposure over the long term and generally result in the highest potential exposures and risk. In an industrial area where redevelopment for homes is not feasible now or in the foreseeable future, future land use planning scenarios would be more accurately reflected as industrial rather than residential. However, to provide a conservative assessment of risk, a residential land use scenario is assumed as one of the potential receptors for this assessment. Consequently, appropriate default parameters and equations for residential land use were evaluated.

Under the residential land use scenario, residents are expected to be continuously exposed to contaminated media. Exposure is higher than that under the industrial scenarios because exposure is more frequent and lasts for a longer duration of time. Exposure is calculated for a lifetime, which includes exposures for the receptor as both child and adult. Pathways are evaluated for exposures to surface soil, sediment, and surface water.

The recreational scenario addresses exposure to children and adults who spend a limited amount of time at or near the site while engaging in outdoor activities. The recreational land use scenario is also referred to as the "trespasser" or "site visitor" scenario. Pathways are evaluated for exposures to surface

soil, sediment, and surface water.

The agricultural scenario assumes a resident is also exposed to homegrown farm products. Exposure routes considered in addition to the residential pathways include the consumption of vegetables, the consumption of whole milk, and the consumption of beef.

2 Soil/ Sediment Exposure Pathways

Exposure pathways evaluated for soil and sediment include incidental ingestion, inhalation, dermal contact, and agricultural pathways.

2.1 Incidental Soil/Sediment Ingestion

The incidental ingestion of soil is a potentially significant source of exposure. Equation 1 (non-radionuclides), Equation 2 (radionuclides), and Table 1 present the exposure variables for the soil/sediment ingestion pathway for the residential, industrial, recreational, and agricultural scenarios. The potential for exposure to children is greater due to behavioral patterns present during childhood. The higher value for children under the non-industrial scenarios are based on fecal tracer studies and account for the ingestion of both indoor and outdoor dust.

$$Nonrad\ Intake_{ing} = \frac{C_{sn} CF_1 EF FI ED IR_{ac}}{CF_2 BW_{ac} AT} \quad Eq. 1$$

$$Rad\ Intake_{ing} = C_{sr} CF_8 EF FI ED IR \quad Eq. 2$$

Table 1. Soil/Sediment Ingestion Parameters

Parameter	Units	Residential	Industrial	Recreational	Agricultural
Non-radionuclide chemical concentration in soil = C_{sn}	mg/kg	Chemical-specific	Chemical-specific	Chemical-specific	Chemical-specific

2.2 Soil/Sediment Inhalation (Residential, Industrial, Recreational)

Equation 3 (non-radionuclides), equation 4 (radionuclides), and Table 2 present the exposure variables for the soil/sediment inhalation pathway for the residential, industrial, recreational, and agricultural scenarios. The particulate emission factor (PEF) is represented by the term that includes V, U_m/U_i, F(x), Q/C, and CF₃. The default PEF in SADA is 1.32E+9 (EPA 1996). The 1/VF term is only present in equation 2 if the contaminant is a volatile.

$$Nonrad\ Intake_{inh} = \frac{C_m EF ED \left(\frac{1}{VF} \left[\frac{0.036 (1-V) (U_m/U_i)^3 F(x)}{(Q/C) CF_3} \right] \right)}{CF_2 AT} \quad Eq. 3$$

$$Rad\ Intake_{inh} = C_{sr} CF_5 EF ED \left(\frac{1}{VF} \left[\frac{0.036 (1-V) (U_m/U_i)^3 F(x)}{(Q/C) CF_3} \right] \right) IR_{air} \quad Eq. 4$$

3 Surface Water/ Groundwater Exposure Pathways

Exposure pathways evaluated for surface water and groundwater include ingestion, indoor inhalation, dermal contact, and agricultural pathways.

3.1 Surface Water/Groundwater Ingestion (Residential, Industrial, Recreational)

Equation 12 (non-radionuclides), equation 13 (radionuclides), and Table 7 present the exposure variables for the surface water/groundwater ingestion pathway. This pathway is conducted for the residential, industrial, and inhalation pathways.

$$Nonrad\ Intake_{ing} = \frac{C_{wm} IR_w EF ED}{CF_2 BW AT} \quad \text{Eq. 12}$$

$$Rad\ Intake_{ing} = C_{wr} IR_w EF ED \quad \text{Eq. 13}$$

Table 7. Surface Water/Groundwater Ingestion Parameters

Parameter	Units	Residential	Industrial	Recreational	Agricultural
-----------	-------	-------------	------------	--------------	--------------

Non-radionuclide chemical concentration in water = C_{wn}	mg/L	Chemical-specific	Chemical-specific	Chemical-specific	Chemical-specific

3.4 Surface Water/Groundwater Produce Ingestion (Agricultural)

Equation 18 (non-radionuclides), equation 19 (radionuclides), and Table 11 present the exposure variables for the surface water/groundwater produce ingestion pathway. The produce ingestion pathway is conducted for the agricultural pathway only.

$$Nonrad\ Intake_{pro\ ing} = \frac{C_{ww} r_{irr} f_{irr} \left[\frac{(BV_{wet} \cdot MLF) (1 - \exp(-\lambda_i t_b))}{P \cdot \lambda_i} \right] \cdot \frac{I_f T (1 - \exp(-\lambda_e t_v))}{Y_v \cdot \lambda_e} \cdot FI_v \cdot IR_v \cdot EF \cdot ED}{CF_2 \cdot BW \cdot AT} \quad Eq. 18$$

$$Rad\ Intake_{pro\ ing} = C_{wr} r_{irr} f_{irr} \left[\frac{(BV_{wet} \cdot MLF) (1 - \exp(-\lambda_i t_b))}{P \cdot \lambda_i} \right] \cdot \frac{I_f T (1 - \exp(-\lambda_e t_v))}{Y_v \cdot \lambda_e} \cdot FI_v \cdot IR_v \cdot EF \cdot ED \quad Eq. 19$$

Table 11. Surface Water/Groundwater Produce Ingestion Parameters

Parameter	Units	Agricultural
Non-radionuclide chemical concentration in water = C_{ww}	mg/L	Chemical-specific
Radionuclide chemical concentration in water = C_{wr}	pCi/L	Chemical-specific
Irrigation rate = r_{irr}	L/m ² day	2.08 (Kennedy and Streng 1992)
Irrigation period = f_{irr}	unitless	0.25 (3 months)

Soil to plant uptake factor (wet) = BV_{wet}	kg/kg	Chemical-specific
Mass loading factor = MLF	unitless	0.26 (Pinder and McLeod 1989)
Effective removal rate = λ_r	1/day	$\lambda_r + \lambda_w$
Soil leaching rate = λ_l	1/day	2.7E-5 (NCRP 1989)
Radionuclide half-life = $\lambda_{1/2}$	1/day	Chemical-specific
Long-term deposition and buildup = t_b	day	10950 (NCRP 1985)
Areal density for root zone = P	kg/m ²	240 (Hoffman et al. 1982)
Interception fraction = I_r	unitless	0.42 (Miller 1980)
Translocation factor = T	unitless	1 (McKone 1994)
Decay for removal on produce = λ_e	1/day	$\lambda_r + 0.693/t_w$ (NCRP 1989)
Weathering half-life = t_w	1/day	14 (NCRP 1985)
Above ground exposure time = t_e	days	60 (NCRP 1985)
Plant yield (wet) = Y_p	kg/m ²	2 (NCRP 1985)
Diet fraction = FI _p	unitless	0.4 (EPA 1989b)
Ingestion rate = IR _p	kg/d	0.2 (EPA 1989b)
Exposure frequency = EF	d/year	350 (EPA 1989a)
Exposure duration = ED	years	30 (EPA 1989a)
Body weight (adult) = BW	kg	70 (EPA 1989a)
Conversion Factor = CF ₂	days/yr	365
Lifetime = LT	years	70 (EPA 1989a)
Averaging time = AT	years	LT (carcinogen) ED (noncarcinogen)

3.5 Surface Water/Groundwater Beef Ingestion (Agricultural)

Equation 20 (non-radionuclides), equation 21 (radionuclides), and Table 12 present the exposure variables for the surface water/groundwater beef ingestion pathway. The beef ingestion pathway is conducted for the agricultural pathway only.

$$Nonrad\ Intake_{beef\ ing} = \frac{C_{wn} Q_w B f IR FI EF ED}{CF_2 BW AT} \quad \text{Eq. 20}$$

$$Rad\ Intake_{beef\ ing} = C_{wr} Q_w B f IR FI EF ED \quad \text{Eq. 21}$$

Table 12. Surface Water/ Groundwater Beef Ingestion Parameters

Parameter	Units	Agricultural
Non-radionuclide chemical concentration in water = C_{wn}	mg/L	Chemical-specific
Radionuclide chemical concentration in water = C_{wr}	pCi/L	Chemical-specific
Quantity of water ingested (cattle) = Q_w	L/day	50 (IAEA 1994)
Beef transfer coefficient = Bf	day/kg	Chemical-specific
Ingestion rate = IR	kg/day	0.075 (EPA 1989b)
Conversion factor = CF	g/kg	1000
Diet fraction = FI	unitless	1
Exposure frequency = EF	day/yr	350 (EPA 1989a)
Exposure duration = ED	years	30 (EPA 1989a)
Body weight = BW	kg	70 (EPA 1989a)
Conversion Factor = CF_2	days/yr	365
Lifetime = LT	years	70 (EPA 1989a)
Averaging time = AT	years	LT (carcinogen) ED (noncarcinogen)

3.6 Surface Water/Groundwater Milk Ingestion (Agricultural)

Equation 22 (non-radionuclides), equation 23 (radionuclides), and Table 13 present the exposure variables for the surface water/groundwater milk ingestion pathway. The milk ingestion pathway is conducted for the agricultural pathway only.

$$Nonrad\ Intake_{milk\ ing} = \frac{C_{wn} Bm Q_w IR_m FI EF ED}{CF_2 BW AT} \quad \text{Eq. 22}$$

$$Rad\ Intake_{milk\ ing} = C_{wr} Bm Q_w IR_m FI EF ED \quad Eq. 23$$

Table 13. Surface Water/Groundwater Milk Ingestion Parameters

Parameter	Units	Agricultural
Non-radionuclide chemical concentration in water = C_{wr}	mg/L	Chemical-specific
Radionuclide chemical concentration in water = C_{wr}	pCi/L	Chemical-specific
Quantity of water ingested (dairy) = Q_w	L/day	75 (IAEA 1994)
Milk transfer coefficient = Bm	day/L	Chemical-specific
Ingestion Rate = IR_m	L/d	0.305 (adult) (EPA 1989b) 0.509 (child) (Pao et al. 1982)
Exposure frequency = EF	d/year	350 (EPA 1989a)
Exposure duration = ED	years	24 (adult) 6 (child) (EPA 1989a)
Body weight = BW	kg	70 (adult) 15 (child) (EPA 1991a)
Conversion Factor = CF_2	days/yr	365
Lifetime = LT	years	70 (EPA 1989a)
Averaging time = AT	years	LT (carcinogen) ED (noncarcinogen)

3.7 Surface Water Fish Ingestion (Recreational)

Equation 24 (non-radionuclides), equation 25 (radionuclides), and Table 14 present the exposure variables for the surface water fish ingestion pathway. The fish ingestion pathway is conducted for the recreational pathway only.

$$Nonrad\ Intake_{milk\ ing} = \frac{C_{wm} B_{fish} IR_{fish} FI EF ED}{CF_2 BW AT} \quad Eq. 24$$

$$Rad\ Intake_{milk\ ing} = C_{wr} B_{fish} IR_{fish} FI EF ED \quad Eq. 25$$

Table 14. Surface Water Fish Ingestion Parameters

Parameter	Units	Agricultural
Non-radionuclide chemical concentration in water = C_w	mg/L	Chemical-specific
Radionuclide chemical concentration in water = C_w	pCi/L	Chemical-specific
Fish transfer coefficient = B_{fish}	day/L	Chemical-specific
Ingestion Rate = IR_m	kg/d	0.054 (adult) (EPA 1991a)
Exposure frequency = EF	d/year	45 (EPA 1995)
Exposure duration = ED	years	30 (EPA 1989a)
Body weight = BW	kg	70 (adult) (EPA 1991a)
Conversion Factor = CF_1	days/yr	365
Lifetime = LT	years	70 (EPA 1989a)
Averaging time = AT	years	LT (carcinogen) ED (noncarcinogen)

4. Toxicity Data

SADA accesses a database of chemical-specific toxicity values that contains the human health toxicological information needed to perform the risk assessments. This database contains toxicity information taken from the United States Environmental Protection Agency's (EPA) Integrated Risk Information System (IRIS), the Health Effects Assessment Summary Tables (HEAST), and other sources. The toxicity database contains a variety of information that is used to either calculate risks or hazards (e.g., cancer slope factors and reference doses, respectively) or to derive dose estimates (e.g., volatilization factor, particulate emission factor). Reference Doses (RfDs), Reference Concentrations (RfCs), slope factors (SFs), and inhalation unit risks (IUR) are values which are used to determine either the potential of a toxic effect (RfD and RfC) or the development of excess cancers (slope factors and unit risks) in a receptor.

4.1 Noncarcinogenic Hazard

RfDs (for ingestion and dermal contact) and RfCs (for inhalation) are used in SADA to determine the hazard quotient based on the intake calculations previously presented. Equation 26 shows how the intake is divided by the RfC or RfD to yield the hazard quotient for a given contaminant and pathway.

$$Hazard \propto \frac{Intake}{RfD \propto RfC} \quad \text{Eq. 26}$$

4.2 Carcinogenic Risk

Slope factors (for ingestion, radionuclide inhalation, dermal contact, and external exposure) and inhalation unit risks (for nonradionuclide inhalation) are used in SADA based on the intake calculations

previously presented. Equation 27 shows how the intake is multiplied by the slope factor or unit risk to determine the carcinogenic risk for a given contaminant and pathway.

$$\text{Risk} = \text{Intake} (SF \times IUR) \quad \text{Eq. 27}$$
